Abstract

**Background:** Oral and dental diseases are among the common health conditions which can have different effects on the individuals’ health and quality of life. The objective of this study was to examine the effect of garlic (*Allium sativum*) extract on saliva *Streptococcus mutans* (primary outcome) and its side effects (secondary outcome).

**Methods:** In the present systematic review and meta-analysis, English and Persian databases (PubMed, Cochrane Library, Google Scholar, Scopus, Web of Science, SID, and Magiran) were systematically searched until February 25, 2021. The quality of the included studies was examined using Cochrane handbook, and the meta-analysis was carried out using RevMan 5.3. Heterogeneity of the studies was analyzed by index I². Moreover, the quality of the evidence was assessed through GRADE approach.

**Results:** A total of 93 studies were found on the databases; 89 articles were screened by title and abstract review and were removed as 19 studies were repetitive and 70 studies were unrelated to the subject under study. Ultimately, 4 articles with a sample size of 171 participants were included in this study, and two of the four studies were meta-analyzed. In all the 4 studies, garlic extract was effective in reducing the number of saliva *Streptococcus mutans* colonies compared to the control group. The results of the meta-analysis showed that using garlic extract mouthwash significantly decreased the average number of saliva *Streptococcus mutans* colonies (Mean Difference: -3.32; 95%CI: -4.39 to -2.26; P<0.00001).

**Conclusion:** Although this review study indicated the significant effect of garlic extract in reducing saliva *Streptococcus mutans*, the evidence is not sufficient enough to recommend garlic extract to fight saliva *Streptococcus mutans*, and more clinical trials with stronger designs and larger sample sizes are needed.

**Key words:** Allicin, Garlic, Streptococcus mutans, Saliva
Introduction

Dental and oral diseases are among the common health conditions which have different effects on the individuals’ quality of life and health. Dental diseases cause pain and discomfort and affect physical functions such as chewing, talking, smiling, and personal-social roles.\(^1\) Caries-causing microorganisms can be controlled with different chemicals and natural agents.\(^2\)

Chlorhexidine and fluorides are among the chemical agents. Chlorhexidine is an antibacterial agent which helps control plaques, eliminate bacteria, and reduce the clinical symptoms of gum inflammation. However, it can also cause undesirable effects such as tooth discoloration, resistance to disinfecting agents, and rare allergic reactions.\(^3\) Regular use of mouthwashes containing with fluoride considerably decreases caries in permanent teeth in children and adolescents.\(^4\) Nonetheless, it can also cause adverse effects.\(^5\) Natural agents such as chemicals extracted from plants are used as effective and economic therapies to prevent dental caries with fewer side effects.\(^2\) The tendency to use the anti-caries properties of natural products that can control bacterial virulence without disrupting the beneficial activity of oral microbiome has been increased in recent years.\(^6\)

Garlic, known as *Allium sativum* L in botany, is one of the natural agents used in dentistry because of its anti-microbial effects.\(^7\) The word garlic in English comes from “garleac”, literally meaning “spear-leek” (gar means spear, referring to the shape of a clove resembling spear, and leac is the Old English form of leek).\(^8\) Garlic has sulfurous components such as allicin, alliin, vinylthiins, sulfides, and ajoenes. Moreover, it has biological properties as it is anti-bacterial, anti-carcinogen, antioxidant, anti-diabetic, anti-atherosclerosis, anti-fungal, and anti-inflammation. Furthermore, it helps kidneys and reduces blood proteins and blood pressure.\(^9\) The anti-bacterial property of garlic is mostly related to allicin, which can be
effective against gram-positive and gram-negative bacteria.\textsuperscript{10} Several laboratory studies have shown the effect of garlic extract in the inhibition of \textit{Streptococcus mutans}.\textsuperscript{11-13}

\textit{Streptococcus mutans} is a gram-positive bacterium and the main cause of dental caries. It can synthetize large numbers of glucan extra-cellular polymers from sucrose, immediately resulting in the permanent colonization of hard surfaces and creation of extra-cellular polymer matrix. Moreover, it can transform and metabolize a vast spectrum of carbohydrates into organic acids and grow in environmental stress, particularly at low pH (acidity).\textsuperscript{14}

\textit{Streptococcus mutans} contributes to severe dental caries, plaques, and endocarditis, which can have serious effects on health.\textsuperscript{15} On the other hand, herbal agents have positive effects with fewer side effects, and dental treatments and general health interventions, so they can improve life quality.\textsuperscript{1} Therefore, the aim of this study was to examine the effect of garlic (\textit{Allium sativum}) extract on salivary \textit{Streptococcus mutans} (primary outcome) and its side effects (secondary outcome).

\textbf{Objectives}

To assess the effect of garlic (\textit{Allium Sativum}) extract on salivary \textit{streptococcus mutans}

\textbf{Materials and Methods}

\textit{PICOS (Participants, Intervention, Comparison group, Outcomes, Study Type)}

All age groups from both genders were included in this systematic review. All clinical trials in which garlic extract was used as an intervention on \textit{Streptococcus mutans} were included regardless of their preparation and production methods, duration of treatments, and dosage. The trials in which the intervention group received garlic extract combined with other herbs were excluded. Also, the trials with control groups taking placebo and other treatments or without intervention were included in this systematic review. The primary and secondary
outcomes showed the effect of garlic extract on saliva *Streptococcus mutans* and its side effects, respectively.

All randomized controlled trials and quasi-experimental trials published in English and Persian were included in this systematic review. Qualitative studies, systematic reviews, observational researches and letters to the editor were excluded from the present systematic review.

**Search strategy**

English databases including PubMed, Cochrane Library, Embase, Google scholar, Scopus, and Web of Science as well as Persian databases including SID and Magiran were systematically searched until February 25, 2021 using the keywords *Streptococcus mutans* [MeSH], garlic [MeSH], saliva [MeSH], and *allium sativum*. Moreover, free keywords were used alongside MeSH keywords. Also, the references of all the included articles were assessed for additional related articles. To search for grey literature (unpublished sources), European Association for Grey Literature Exploitation (EAGLE) and Health Care Management Information Consortium (HMIC) were investigated. For example, the search strategy for PubMed database was as follows:

(((("Garlic"[Mesh]) OR (Garlic)) OR (Allium)) OR (allicin)) OR (allium sativum)) AND ((("Saliva"[Mesh]) OR (saliva)) OR (salivas))) AND ("Streptococcus mutans"[Mesh])

**Selection of studies and Data extraction**

The eligibility of the studies was analyzed by two authors (MT, MM) independently. The disagreement between the authors on the eligibility of the studies was resolved by discussion and, in cases of disagreement, by consulting a third party (MM). Furthermore, the references of the included studies were examined.
The data extraction form was designed based on the Cochrane handbook for systematic reviews of interventions\textsuperscript{16} including the author’s name, publication year, country, clinical trial type, sample size, participants’ age, intervention, control group, measurement instrument, results and side effects. Two authors (MT, MM) extracted the information of the studies independently.

\textit{Evaluation of the risk of bias in the included studies}

Two authors (MT, MM) independently examined the risk of bias in terms of randomization, concealment of allocation, blinding, incomplete outcome data, and selective outcome reporting for all the studies based on the criteria in Cochrane Handbook.\textsuperscript{17} According to the Handbook, the risk of bias was assessed as low risk, high risk and unclear risk. Next, any disagreement between the authors was resolved by discussion, and a third author (MM) was consulted if required.

The evidence quality was assessed using the GRADE approach in the four categories of high, moderate, low and very low.\textsuperscript{18} Based on this method, the random controlled experiments that do not have serious limitations are evaluated as high quality. However, the general quality of the evidence can be reduced with the presence of each one of the following factors: indirectness of the evidence, imprecision of the results, high likelihood of bias, inconsistency of the results or unexplained heterogeneity, and publication bias.

\textit{Data analysis}

RevMan was used for meta-analysis.\textsuperscript{19} The mean difference (95% confidence interval) was considered for continuous outcomes. Heterogeneity was identified by I squared (I\textsuperscript{2}) statistic. Heterogeneity >50% with p-value <0.1 were considered as the criteria for judgement.

\textit{Ethical consideration}
The study was reviewed and approved by Ethics Committee of Tabriz University of Medical Sciences (code: IR.TBZMED.REC.1399.1113). All the methods were performed in accordance with the Declaration of Helsinki.

**Results**

**Results of the search**

In total, 93 articles were obtained from the databases; 89 articles were screened by title and abstract review and were removed as 19 studies were repetitive and 70 studies were unrelated to the subject under study. Four articles were included in this systematic review, and two trials, in which the effects of garlic extract on saliva *Streptococcus mutans* were reported as mean (standard deviation) compared with the control group were entered into the meta-analysis (Figure 1).

**Information on the included studies**

Table 1 indicates the information on the included trials. The participants were divided into 4 groups in two of the trials\(^{20,21}\) and into 3 groups in the other two trials.\(^ {22,23}\) In Chavan et al., study\(^ {22}\), the effect of garlic extract mouthwash was compared to that of chlorhexidine 0.2% as well as Sorbitol 5% and Spearmint oil 5% (control group); in Padiyar et al., study\(^ {20}\), it was compared to Triphala mouthwash and chlorhexidine 0.2%; in Prabhakar et al., study\(^ {20}\), it was compared to tea tree 0.2% mouthwash, curry leave mouthwash 2.5% and placebo group; and in Groppo et al., study\(^ {23}\), it was compared to chlorhexidine 1.2% and tea tree 0.2%.

The mouthwashes were used as follows: 10 mL before sleep for a week,\(^ {22}\) 10 mL once a day for 15 days,\(^ {20}\) 10 mL twice a day for seven days,\(^ {21}\) and 10 mL once a day for 7 days\(^ {23}\) in the studies by Chavan et al., Padiyar et al., Prabhakar et al., and Groppo et al., respectively. The sample size was 171 in the included studies and ranged from 30 participants in the study by Groppo et al.\(^ {23}\) to 60 participants in the study by Padiyar et al.\(^ {20}\) All the included studies
were carried out in India. The participants in the included review studies were school children (9-12 age group) and adults (18-35 age group). Saliva samples were taken from the participants for microbiological evaluation in order to examine the effect of garlic extract mouthwash, and Streptococcus mutans colony forming unit was measured in the laboratory after preparation.

In the study by Chavan et al. (2010), saliva Streptococcus mutans count was significantly lower with 3.82 (1.33) in 2.5% garlic extract mouthwash compared with that in the chlorhexidine group with 5.62 (2.17) and the control group with 6.4 (2.16) (p<0.05). The side effect of garlic extract mouthwash was a burning sensation after use as all of the participants complained about it.

In the study by Padiyar et al. (2018), saliva Streptococcus mutans count was significantly different in the four study groups. However, chlorhexidine mouthwash was more effective in reducing Streptococcus mutans compared with garlic extract and Triphala mouthwashes and the control group (P<0.05). The mean (SD: standard deviation) of Streptococcus mutans counts were reported 1.24 (0.33), 1.93 (0.38), 2.31 (0.43), and 6.03 (0.55) in chlorhexidine, Triphala, garlic extract, and control groups, respectively. Streptococcus mutans count was significantly lower in garlic extract group compared with that in the control group (P<0.05). This study did not report the side effects of garlic extract mouthwash.

In the trial by Prabhakar et al. (2009), saliva Streptococcus mutans count in garlic extract group significantly decreased after using the mouthwash compared with pre-treatment count. The reported side effects for garlic extract mouthwash were bad taste, burning sensation, bad odor, and nausea.
In the trial by Groppo et al. (2002), the results indicated that the average *Streptococcus mutans* count was lower than pre-treatment average count in garlic extract group after the first, second, and third weeks of intervention ($p<0.05$). The side effects such as bad odor, burning sensation, and worse breath were significantly more pronounced in garlic extract group than in chlorhexidine and tea tree groups ($p<0.05$).

**Results of risk of bias evaluation**

The participants were randomly assigned to the study groups in all the trials included in this systematic review; thus, random sequence generation was considered low risk. There was no explanation on allocation concealment in the included trials and, as a result, it was considered as unclear-risk. Only one study\(^\text{20}\) had blinding of participants and blinding of outcome assessor; therefore, blinding was considered as low risk in this study and as unclear risk in the other trials. Bias related to incomplete outcome data was low risk in all the four studies as all the participants completed the study. Selective reporting bias was low risk as all the outcomes were reported in all the studies. Moreover, other biases were low-risk in all the four studies (Figures 2 and 3).

**Results of meta-analysis**

The meta-analysis results of two trials indicated that using garlic extract mouthwash decreased the number of saliva *Streptococcus mutans* colonies compared with the control group (mean difference $=-3.32$ CFU/m $\times 10^5$; $95\%$ CI: -4.39 to -2.26; $P<0.00001$). The heterogeneity level was moderate ($I^2=64\%, p=0.09$). Due to high heterogeneity, random effect was reported instead of fixed effect (Figure 4).

According to the GRADE approach regarding the comparison between garlic extract group and control group, the evidence was low quality. Therefore, the results were close to reality with low confidence. The results of evidence quality assessment by GRADE are shown
in Table 2. Since the number of the studies included in the meta-analysis was smaller than 10, the graphical or statistical methods were not used to assess publication bias.\textsuperscript{16}

**Discussion**

According to the results, there was a significant statistical difference between intervention and control groups regarding the average number of saliva *Streptococcus mutans*. However, due to the insufficient number of the included RCTs and the total sample size, a final conclusion cannot be drawn for the effectiveness of garlic extract on saliva *Streptococcus mutans*.

Garlic has been known as an alternative therapy used to treat infectious diseases for years.\textsuperscript{24,25} Moreover, some laboratory studies have shown the positive effect of garlic in controlling *Streptococcus mutans*.\textsuperscript{22,26} The anti-bacterial property of garlic is mostly attributed to allicin, which acts through the chemical reactions with thiol-containing enzymes such as RNA polymerase, thioredoxin reductase, and alcohol dehydrogenase. In addition, allicin has shown an interesting potential in general healthcare; in fact, its antioxidant and immunomodulatory effects arise from mechanisms that may define their potential in inhibiting apoptosis proliferation and induction in different human cancers.\textsuperscript{27} Nevertheless, allicin, the active component of garlic, could stimulate the stomach, particularly in high doses. Additionally, it has been reported that garlic affects the pharmacokinetics of antiviral drugs and anticoagulants. Therefore, these points need to be taken into consideration when garlic is taken as a medicine to treat various diseases.\textsuperscript{9}

*Streptococcus mutans* strains produce up to three glycosyltransferase (GtfB, GtfC, and GtfD) and use the glucose moiety of sucrose for synthesizing glucose glucan polymers.\textsuperscript{14} Increased number of saliva *Streptococcus mutans* results in more dental caries.\textsuperscript{28} Live/dead staining following confocal laser scanning microscopy analysis shows that allicin has a bactericidal effect on the *Streptococcus mutans* developed in the biofilms (dental plaque).\textsuperscript{29}
Therefore, the mechanism of the effect of garlic on the number of *Streptococcus mutans* colonies can be explained by considering the antibacterial effects of allicin in the garlic on thiol-containing enzymes,\textsuperscript{27} which are essential for bacterial nutrition.\textsuperscript{30}

Burning sensation, bad odor, nausea, and worse breath were reported as garlic extract side effects in the trials included in this systematic review. Garlic is an herbal medicine which has proved tolerable with the fewest side effects in the trials. No severe side effect has been reported even though most of the participants complained about its bad odor.\textsuperscript{31} Smelly breath and body odor have been reported in different studies as some side effects of garlic taken orally. Other unproven side effects have been stomachache, esophagus burn, asthma, and bleeding.\textsuperscript{32} Although no severe side effect has been reported for garlic, bad odor in oral ingestion form could limit its use.\textsuperscript{33}

**Strengths and limitations**

This was the first review study on the effect of garlic extract on saliva *Streptococcus mutans*. In all the four included studies, the participants were randomly assigned to intervention and control groups and there was no participant drop-out. Although there was no information on blinding in some studies, it could not distort the results as the endpoint of the studies was the number of *Streptococcus mutans* and a non-subjective outcome. Some weak points of this study could be the limited number of the included studies and the small sample size. Also, this study was not registered in PROSPERO or similar databases.

**Conclusion**

This review study indicated the significant effects of garlic extract in reducing saliva *Streptococcus mutans*. However, there is still not sufficient evidence to recommend garlic extract to fight saliva *Streptococcus mutans*, so further clinical trials with stronger designs and
larger sample sizes are needed for better conclusions. Moreover, due to the language limitation, it cannot be assured that all the trials were included in this review.

**Ethical Issues**

The study was reviewed and approved by Ethics Committee of Tabriz University of Medical Sciences (code: IR.TBZMED.REC.1399.1113). All methods were performed in accordance with the Declaration of Helsinki.

**Acknowledgement**

The authors appreciate the assistance of the Research Deputy of Tabriz University of Medical Sciences for approving and supporting this study financially.

**Conflict of Interest**

The authors declare that they have no competing interests.
